Xylocaine® Pump Spray 10% (10 mg/dose)

Pump spray for topical anaesthesia

Composition

Active constituent:

1 dose Xylocaine pump spray contains: Lidocaine base 10 mg.

Therapeutic indications

For the prevention of pain associated with the following procedures:

Otorhinolaryngology

- Puncture of the maxillary sinus and minor surgical procedures in the oral and nasal cavity, pharynx and epipharynx.
- Paracentesis.

Obstetrics

During the final stages of delivery and before episiotomy and perineal suturing as supplementary pain control.

Introduction of instruments, tubes and catheters into the respiratory and digestive tract

Provides surface anaesthesia for the oropharyngeal and tracheal areas to reduce reflex activity, attenuate haemodynamic responses and facilitate insertion of the tube or the passage of instruments during endotracheal intubation and endoscopic procedures of the airways and upper gastrointestinal tract.

Dental practice

Before injections, dental impressions, X-ray photography, removal of calculus.

Dosage and method of administration

Xylocaine spray is intended for use on mucous membranes and provides efficient surface anaesthesia, which lasts for approximately 10-15 minutes. The anaesthesia usually occurs within 1-5 minutes, depending on the area of application.

As with any local anaesthetic, the safety and effectiveness of lidocaine depend on the proper dosage, the correct technique, adequate precautions and readiness for emergencies.

The following dosage recommendations should be regarded as a guide. The clinician's experience and knowledge of the patient's physical status are of importance in calculating the required dose.

The degree of absorption from mucous membranes is variable but especially high from the bronchial tree. Application only to areas below the vocal cords may result in excessive plasma concentrations because of less transfer to the intestine and less first-pass loss.

Each actuation of the metered-dose valve delivers 10 mg Xylocaine base. It is unnecessary to dry the site prior to application.

Otorhinolaryngology: 3 metered doses for puncture of the maxillary sinus or other minor surgical procedures.

- Paracentesis: 3 metered doses.
- During delivery: Up to 20 metered doses (200 mg lidocaine base).
- Introduction of instruments, tubes and catheters into the respiratory and digestive tract: Up to 20 metered doses (200 mg lidocaine base) for procedures in pharynx, larynx and trachea. During prolonged procedures up to 400 mg of lidocaine may be administered. In addition, when combined with other lidocaine products, the total dose should not exceed 400 mg. With applications mainly to the larynx, trachea and bronchi, the dose should not exceed 20 metered doses (200 mg lidocaine base).
- Dental practice: 1-5 metered doses to the mucous membranes.

Debilitated or elderly patients, children over 12 years of age, acutely ill patients or patients with sepsis should be given doses commensurate with their age, weight and physical condition.

In children less than 12 years of age the dose should not exceed 3 mg/kg (e.g. 6 metered doses in an infant weighing 20 kg). When used mainly in the larynx and trachea the dose should be reduced to 1.5 mg/kg. In children less than 3 years of age less concentrated lidocaine solutions are recommended.

Contraindications

Known history of hypersensitivity to local anaesthetics of the amide type or to other components of the spray solution.

Special warnings and special precautions for use

Excessive dosage or short intervals between doses, may result in high plasma levels and serious adverse effects. Absorption from mucous membranes is variable but is especially high from the bronchial tree. Lidocaine spray should be used with caution in patients with wounds or traumatized mucosa in the region of the proposed application. A damaged mucosa will permit increased systemic absorption. The management of serious adverse reactions may require the use of resuscitative equipment, oxygen and other resuscitative drugs. (See "Overdosage".)

In paralysed patients under general anaesthesia, higher blood concentrations may occur than in spontaneously breathing patients. Unparalysed patients are more likely to swallow a large proportion of the dose which then undergoes considerable first-pass hepatic metabolism following absorption from the gut.

The oropharyngeal use of topical anaesthetic agents may interfere with swallowing and thus enhance the danger of aspiration. Numbness of the tongue or buccal mucosa may increase the danger of biting trauma.

If the dose or administration is likely to result in high blood levels, some patients require special attention to prevent potentially dangerous side effects:

- Patients with partial or complete heart block.
- The elderly and patients in poor general health.
- Patients with advanced liver disease or severe renal dysfunction.

Avoid contact with the eyes.

Interactions with other medicaments and other forms of interaction

Lidocaine should be used with caution in patients receiving agents structurally related to local anaesthetics, e.g. tocainide, since the toxic effects are additive.

Pregnancy and lactation

It is reasonable to assume that a large number of pregnant women and women of child-bearing age have been given lidocaine. No specific disturbances to the reproductive process have so far been reported, e.g. no increased incidence of malformations.

Like other local anaesthetics lidocaine may enter the mother's milk, but in such small amounts that there is generally no risk of this affecting the neonate.

Effects on ability to drive and use machines

Depending on the dose, local anaesthetics may have a very mild effect on mental function and may temporarily impair locomotion and coordination.

Undesirable effects

Local reactions

Local irritation at the application site has been described. Following application to laryngeal mucosa before endotracheal intubation, reversible symptoms such as "sore throat", "hoarseness" and "loss of voice" have been reported. The use of Xylocaine spray provides surface anaesthesia during an endotracheal procedure but does not prevent post-intubation soreness.

Allergic reactions

Allergic reactions (in the most severe instances anaphylactic shock) to local anaesthetics of the amide type are rare.

Acute systemic toxicity

Lidocaine may cause acute toxic effects if high systemic levels occur due to rapid absorption or overdosage. (See "Pharmacodynamic properties" and "Overdosage".)

Overdosage

Acute systemic toxicity

Toxic reactions originate mainly in the central nervous system and the cardiovascular system.

Central nervous system toxicity is a graded response with symptoms and signs of escalating severity. The first symptoms are circumoral paraesthesia, numbness of the tongue, light-headedness, hyperacusis and tinnitus. Visual disturbance and muscular tremors are more serious and precede the onset of generalized convulsions. Unconsciousness and grand mal convulsions may follow, which may last from a few seconds to several minutes. Hypoxia and hypercarbia occur rapidly following convulsions due to the increased muscular activity, together with the interference with normal respiration. In severe cases apnoea may occur. Acidosis increases the toxic effects of local anaesthetics.

Recovery is due to redistribution and metabolism of the local anaesthetic drug from the central nervous system. Recovery may be rapid unless large amounts of the drug have been administered.

Cardiovascular effects are only seen in cases with high systemic concentrations. Severe hypotension, bradycardia, arrhythmia and cardiovascular collapse may be the result in such cases.

Cardiovascular toxic effects are generally preceded by signs of toxicity in the central nervous system, unless the patient is receiving a general anaesthetic or is heavily sedated with drugs such as a benzodiazepine or barbiturate.

Treatment of acute toxicity

Treatment of acute toxicity should be instituted at the latest when twitches occur. The necessary drugs and equipment should be immediately available. The objectives of treatment are to maintain oxygenation, stop the convulsions and support the circulation.

Oxygen must be given and, if necessary, assisted ventilation (mask and bag). An anticonvulsant should be given i.v. if the convulsions do not stop spontaneously in 15-20 sec. Thiopentone 100-150 mg i.v. will abort the convulsions rapidly. Alternatively diazepam 5-10 mg i.v. may be used although its action is slower. Suxamethonium will stop the muscle convulsions rapidly, but will require tracheal intubation and artificial ventilation, and should only be used by those familiar with these procedures. If cardiovascular depression is evident (hypotension, bradycardia), ephedrine 5-10 mg i.v. should be given and repeated, if necessary, after 2-3 min.

Should circulatory arrest occur, immediate cardiopulmonary resuscitation should be instituted. Optimal oxygenation and ventilation and circulatory support as well as treatment of acidosis are of vital importance, since hypoxia and acidosis will increase the systemic toxicity of local anaesthetics. Adrenaline (0.1-0.2 mg as intravenous or intracardiac injections) should be given as soon as possible and repeated, if necessary.

Children should be given doses commensurate with their age and weight.

Pharmacological properties

Description

Xylocaine pump spray is intended for use on mucous membranes and provides an efficient surface anaesthesia, which lasts for approximately 10-15 minutes. The anaesthesia usually occurs within 1-5 minutes depending on the area of application.

Pharmacodynamic properties

Lidocaine, like other local anaesthetics, causes a reversible blockade of impulse propagation along nerve fibres by preventing the inward movement of sodium ions through the nerve membrane. Local anaesthetics of the amide type are thought to act within the sodium channels of the nerve membrane.

Local anaesthetic drugs may also have similar effects on excitable membranes in the brain and myocardium. If excessive amounts of drug reach the systemic circulation rapidly, symptoms and signs of toxicity will appear, emanating from the central nervous and cardiovascular systems.

Central nervous system toxicity (see "Overdosage") usually precedes the cardiovascular effects since it occurs at lower plasma concentrations. Direct effects of local anaesthetics on the heart include slow conduction, negative inotropism and eventually cardiac arrest.

Pharmaceutical particulars

Excipients

Ethanol, Polyethylene glycol 400, Essence of banana, Menthol, Saccharin, Water, purified

Special precautions for storage

Do not store above 25°C. During storage at temperatures below 8°C precipitation may occur. This precipitation is dissolved when warming up in room-temperature.

Instructions for use/handling

The nozzle must not be shortened, otherwise the spray function will be destroyed. If cleaning of the nozzle is desired, the entire nozzle can be submersed in boiling water for 5 minutes. The nozzle can be autoclaved (20 minutes at 120°C).
